

- 1、消息机制与触摸处理的机制是类似的最关键的时异步线程的唤醒。当然如果是自己就没必要了
- 2、`void` `Looper::wake()` { `nWrite` = `write(mWakeWritePipeFd, "W", 1);`}
- 3、记得是唤醒。不可能无缘无故就有办法访问另一个线程

sMainThreadHandler与mH

Looper

MessageQueue

ThreadLocal

如果想要在一个线程中出创建Handler，就必须开启Looper循环

```
1. int pid = Process.start("android.app.ActivityThread",
2.     mSimpleProcessManagement ? app.processName : null, uid, uid,
3.     gids, debugFlags, null);
```

Handler是不是与触摸事件不太一致

```
1.
2. enqueueMessage(Message msg, long when) {
3.     .....
4.
5.     final boolean needWake;
6.     synchronized (this) {
7.         .....
8.
9.         msg.when = when;
10.        //Log.d("MessageQueue", "Enqueing: " + msg);
11.        Message p = mMessages;
12.        if (p == null || when == 0 || when < p.when) {
13.            msg.next = p;
14.            mMessages = msg;
15.            needWake = mBlocked; // new head, might need to wake up
16.        } else {
17.            Message prev = null;
18.            while (p != null && p.when <= when) {
19.                prev = p;
20.                p = p.next;
21.            }
22.            msg.next = prev.next;
23.            prev.next = msg;
24.            needWake = false; // still waiting on head, no need to wake up
25.        }
26.
27.    }
28.    if (needWake) {
29.        nativeWake(mPtr);
30.    }
31.}
32.
33.可以看出其实和其他InputManager通知的原理是一样的
34.
35.void Looper::wake() {
36.    .....
37.
38.    ssize_t nWrite;
39.    do {
40.        nWrite = write(mWakeWritePipeFd, "W", 1);
41.    } while (nWrite == -1 && errno == EINTR);
42.
43.    .....
44.}
```
